Description

Background of the Invention

Field of the Invention

[0001] The present invention relates to a behavior control of a vehicle such as protecting a vehicle from spinning or drifting out, and more particularly, to a behavior control device of a vehicle adapted to estimate a saturation of the tire grip based upon a deviation of a yaw rate detected by a yaw rate sensor relative to a yaw rate calculated based upon vehicle speed and steering angle, for executing a control of the brake system of the vehicle to generate a turning moment in the vehicle acting against a spinning or a drifting out.

Description of the Prior Art

[0002] Such a control is known from document EP-A-0 392 165, which describes the features of the preamble of claim 1.

[0003] It is already known as described in, for example, Japanese Patent Laid-open Publication G-115418, to execute a behavior control of a vehicle against a spinning or a drifting out by detecting that the tire grip condition is approaching a saturation based upon the above-mentioned deviation of the yaw rate. In order to accomplish such a behavior control satisfactorily, it is essential that the above-mentioned yaw rate deviation is estimated at a high precision.

[0004] However, the yaw rate sensors available to date are generally not definite in the performance thereof until they are substantially warmed up. Particularly, the presently available yaw rate sensors generally produce individually different outputs around a neutral point thereof according to each product. Such a fluctuation of the neutral point directly affects the precision of the estimation of the tire grip based upon the deviation of a yaw rate detected by the yaw rate sensor relative to a yaw rate calculated from vehicle speed and steering angle, rendering a behavior control based upon the estimation of the tire grip to be often improper in the warming up period of the yaw rate sensor.

Summary of the Invention

[0005] In view of the above, it is a primary object of the present invention to provide an improved behavior control device of a vehicle having a vehicle body, a plurality of wheels suspended by the vehicle body, an engine, a steering system, and a brake system for selectively braking the wheels, the device comprising means for detecting vehicle speed, means for detecting steering angle, means for detecting yaw rate of the vehicle, and means for controlling the brake system according to a calculation based upon the vehicle speed detected by the vehicle speed sensor, the steering angle detected

by the steering angle sensor, and the yaw rate detected by the yaw rate sensor such that, when a deviation of the yaw rate detected by the yaw rate sensor relative to a standard yaw rate estimated from the vehicle speed and the steering angle increases beyond a threshold value, at least one of the wheels is braked by the brake system so as to generate a yaw moment in the vehicle body for decreasing the deviation of the yaw rate, wherein any improper behavior control due to a neutral shift of the yaw rate sensor before the warming up thereof is definitely avoided.

[0006] According to the present invention, the above-mentioned primary object is accomplished by that the behavior control device of the above-mentioned basic construction is improved such that the control means temporarily increases the threshold value to be higher until the yaw rate sensor is warmed up.

[0007] In the above-mentioned improvement, the warm-up of the yaw rate sensor may be judged by a predetermined time having lapsed from the start of the engine.

[0008] In the above-mentioned improvement, the control means may gradually decrease the magnitude of the increase of the threshold value according to the lapse of time from the increase thereof.

[0009] As an embodiment of the present invention, the control means may calculate an equivalent of the steering angle by a neutral shift of the yaw rate sensor when the vehicle is running straight so as thereby to modify the steering angle detected by the steering angle sensor for a compensation of the neutral shift of the yaw rate sensor, and may annul the temporal increase of the threshold value at least for a predetermined period after an execution of the compensation even when the yaw rate sensor is not yet warmed up. In this case, the control means may calculate the equivalent of the steering angle by the neutral shift of the yaw rate sensor as a mean value of each instant value thereof during a predetermined unit period. Further, the control means may modify the value of the yaw rate detected by the yaw rate sensor so as to compensate for a neutral shift of the yaw rate sensor according to an output thereof while the vehicle is stopped or running straight. Further, the control means may calculate the neutral shift of the yaw rate sensor as a mean value of an instant value thereof during a predetermined unit period.

Brief Description of the Drawings

[0010] In the accompanying drawings,

Fig. 1 is a diagrammatical plan view of a vehicle, showing parts and constructions thereof concerned with the present invention;

Fig. 2 is a flowchart showing an embodiment of the present invention from an aspect of the operation thereof;

Fig. 3 is a flowchart showing a sub-routine incorpo-

rated in the flowchart of Fig. 2;

Fig. 4 is also a sub-routine incorporated in the flowchart of Fig. 2;

Fig. 5 is a map showing an example of the performance of the driftout suppress braking force B_d described hereinbelow relative to the absolute value of the yaw rate deviation $\Delta\gamma$;

Fig. 6 is a diagrammatical plan view of a vehicle during a driftout suppress control;

Fig. 7 is a map showing an example of the performance of the spin suppress braking force B_s described hereinbelow relative to the absolute value of the yaw rate deviation $\Delta\gamma$; and

Fig. 8 is a diagrammatical plan view of a vehicle during a spin control.

Description of the Preferred Embodiments

[0011] In the following, the present invention will be described in more detail with respect to a preferred embodiment with reference to the accompanying drawings.

[0012] Referring to Fig. 1, a vehicle in which the present invention is incorporated in the form of an embodiment has a vehicle body 12, front left, front right, rear left and rear right wheels 10FL, 10FR, 10RL and 10RR suspended by the vehicle body 12, an engine not shown in the figure, and a brake system for selectively braking the wheels, the brake system including wheel cylinders 24FL, 24FR, 24RL and 24RR adapted to apply friction forces to the corresponding brake disks (not shown) of the front left, front right, rear left and rear right wheels, respectively, an oil circuit 22 for selectively supplying raised oil pressure to each of the wheel cylinders, and a combination of a brake pedal 26 and a master cylinder 28 connected with the oil circuit 22 for selectively raising the oil pressure supplied to the wheel cylinders according to a depression of the brake pedal by a driver. An electric controller 30 forming a brain of the behavior control device is constructed substantially by an electronic computer adapted to control the oil circuit 22 according to certain calculations based upon various parameters including at least wheel speed of each wheel detected by wheel speed sensors 32FL, 32FR, 32RL and 32RR for the front left, front right, rear left and rear right wheels, respectively, steering angle detected by a steering angle sensor 34, yaw rate detected by a yaw rate sensor 36, and lateral acceleration detected by a lateral acceleration sensor 38.

[0013] The construction of the behavior control device shown in Fig. 1 will be described hereinbelow from an aspect of the operation thereof by referring to the flowcharts shown in Figs. 2-4.

[0014] Referring to Fig. 2, showing an overall flow of operation, when the control is started by a closure of an ignition switch not shown in the figure, in step 10 signals are read in from those sensors shown in Fig. 1, including wheel speed V_{fl} , V_{fr} , V_{rl} and V_{rr} detected by the wheel speed sensors 32FL, 32FR, 32RL and 32RR, respec-

tively, steering angle θ from the steering angle sensor 34, yaw rate γ from the yaw rate sensor 36, and lateral acceleration G_y from the lateral acceleration sensor 38.

[0015] In step 20, a standard yaw rate γ_t which is a yaw rate estimated to be due based upon the vehicle speed and the steering angle when the tire grip is firm is calculated according to the following equations 1 and 2:

$$\gamma_c = (\theta - \theta_0) V / (R \cdot H) - K_h \cdot G_y \cdot V \quad (1)$$

$$\gamma_t = \gamma_c / (1 + T \cdot s) \quad (2)$$

[0016] In the above equations, V is vehicle speed which may be obtained from an average of wheel speeds V_{fl} - V_{rr} or one of them considered to be slipping the least at each moment, R is a steering gear ratio, H is a wheel base, K_h is a proportioning factor, T is a time constant, s is the Laplace operator, and θ_0 is an equivalent by steering angle of a neutral shift of the yaw rate sensor 36, the equivalent θ_0 being described in more detail hereinbelow.

[0017] In step 30, a deviation $\Delta\gamma$ of the yaw rate detected by the yaw rate sensor 36 relative to the standard yaw rate is calculated according to the following equation 3:

$$\Delta\gamma = \gamma_t - \gamma - \gamma_d \quad (3)$$

[0018] In the above equation 3, γ_d is a neutral shift of the yaw rate sensor 36 calculated directly from the output of the yaw rate sensor 36 when the vehicle is running straight or stopped as described in detail hereinbelow with reference to Fig. 4. In equation 3, the term of γ_d may be omitted for a first convenience, with omission of the processing shown in the flowchart of Fig. 4.

[0019] In step 40, the above-mentioned equivalent θ_0 by steering angle of the neutral shift of the yaw rate sensor 36 is calculated according to the processes shown in Fig. 3, the details of which will be described later.

[0020] In step 45, the neutral shift γ_d of the yaw rate sensor 36 is calculated according to the flowchart of Fig. 4, the details of which will be described later.

[0021] In step 50, it is checked if a predetermined time T_1 has lapsed from the moment when the ignition switch was turned on. When the answer is no, the control proceeds to step 60.

[0022] In step 60, it is checked if a predetermined time T_2 has lapsed from the moment when the calculation of the neutral shift equivalent θ_0 according to the flowchart of Fig. 3 was once finished. When the answer is yes, the control proceeds to step 70.

[0023] In step 70, a stolidity γ_0 of the output of the yaw rate sensor 36 for an increase of the threshold value

for executing the behavior control described hereinbelow with respect to steps 100-160 is calculated according to the following equation:

$$\gamma_o = \gamma_{dmax} \cdot (1 - a^{-1}) \quad (4)$$

[0024] In the above equation 4, γ_{dmax} is a maximum value of the stolidity, "a" is an appropriate base of the exponential function, and t is the time lapsed from the moment of closing the ignition switch.

[0025] In step 80, the threshold value $\Delta\gamma_h$ for judging the deviation $\Delta\gamma$ of the yaw rate γ detected by the yaw rate sensor 36 relative to the standard yaw rate γ_t estimated from the vehicle speed and the steering angle for executing the behavior control according to steps 100-160, is increased by the stolidity γ_o .

[0026] When the answer of step 50 is yes, i.e. when the time T1 has lapsed from the moment of closing the ignition switch so that the yaw rate sensor 36 may be deemed to have warmed up enough, with the neutral shift thereof being settled to a stable value, the control bypasses steps 60 and 70, so as to proceed directly to step 90. Further, when the answer of step 60 is no, i.e. when the time T2 has not yet lapsed from the calculation or renewal of the neutral shift equivalent θ_o in step 40, the control also proceeds directly to step 90, without modifying the threshold value $\Delta\gamma_h$ by the stolidity γ_o of the yaw rate sensor 36 even in a non-warmed-up condition of the yaw rate sensor.

[0027] The value of γ_{dmax} is determined to be a maximum value of the stolidity γ_o just after a cold start of the engine, and therefore the yaw rate sensor. The exponential base "a" is determined in relation to the unit of time "t", so that the stolidity γ_o is gradually decreased at a desirable rate according to the lapse of time from the start of the engine to be substantially cancelled when the yaw rate sensor 36 reaches a desirably warmed up condition.

[0028] In step 90, it is checked if the absolute value of the deviation $\Delta\gamma$ of the yaw rate detected by the yaw rate sensor 36 and the standard yaw rate estimated based upon the vehicle speed and the steering angle is larger than the threshold value $\Delta\gamma_h$. When the answer is no, the control returns to step 10, and no behavior control is executed. On the other hand, when the answer is yes, the control proceeds to step 100.

[0029] In step 100, it is checked if $\Delta\gamma$ is positive. In the above-mentioned processes through steps 10-90, the parameters distinctive of the direction of turn of the vehicle are made positive when the vehicle is turning to the left, while the parameters are made negative when the vehicle is turning to the right. When the answer of step 100 is yes, the control proceeds to step 110, whereas when the answer of step 100 is no, the control proceeds to step 140.

[0030] In step 110, it is checked if the vehicle is turning

to the left. When the answer is yes, the situation is judged such that the vehicle is turning to the left with the actual yaw rate γ being behind the theoretical standard yaw rate γ_t estimated from the vehicle speed and the steering angle, i.e. the vehicle is drifting out. Therefore, the control proceeds to step 120, and a driftout control is executed. In contrast, when the answer of step 110 is no, the situation is such that the vehicle is turning to the right with the actual yaw rate γ advancing the theoretical standard yaw rate γ_t , i.e. the vehicle is spinning. Therefore, the control proceeds to step 130, and a right spin control is executed.

[0031] In step 140, it is checked if the vehicle is turning to the right. When the answer is yes, the situation is such that the vehicle is turning to the right with the actual yaw rate γ being behind to the theoretical standard yaw rate γ_t , i.e. the vehicle is drifting out. Therefore, the control proceeds to step 150, and a driftout control is executed. In contrast, when the answer of step 140 is no, the situation is such that the vehicle is turning to the left with the actual yaw rate γ advancing the theoretical standard yaw rate γ_t , i.e. the vehicle is spinning to the left. Therefore, the control proceeds to step 160, and a left spin control is executed.

[0032] The driftout control, the right spin control and the left spin control executed in step 120 or 150, step 130 and step 160 will be described later in more detail with reference to Figs. 5-8.

[0033] Fig. 3 is a flowchart of a sub-routine executed in step 40 of Fig. 2. According to this sub-routine, in step 41, it is checked if the vehicle is running straight. The judgment may be made based upon the output of the lateral acceleration sensor 38 or a limit switch (not shown) for detecting the neutral position of the steering system. When the answer is no, the process according to this sub-routine is immediately ended. Further, even when the control has once proceeded through steps 42-45 as described hereinbelow, the control is immediately stopped anytime when the answer of step 41 turns into no. When the control is ended directly from step 41, a time parameter Ta described in more detail hereinbelow is reset to zero in step 48. When the answer of step 41 is yes, i.e. the vehicle is running straight, the control proceeds to step 42, and the time parameter Ta is incremented by a small time unit ΔT .

[0034] In step 43, an instant equivalent θ_o by steering angle of a neutral shift $\Delta\gamma$ of the yaw rate sensor 36 is calculated according to the following equation, by using the steering gear ratio R, the wheel base H and the vehicle speed V referred to in step 20:

$$\theta_o = \Delta\gamma \cdot R \cdot H/V \quad (5)$$

[0035] As will be noted, the above process is to compensate for the neutral shift of the yaw rate sensor 36 in a feedback manner effected through the calculation of equation 1. In the shown embodiment of the invention,

in order to avoid too frequent feedback modification of the steering angle θ a time based mean value of θ is calculated, so as to provide θ_o as described hereinbelow.

[0036] In step 44, each instant value of θ is added up to the value of θ_o obtained in the preceding cycles through steps 41-47.

[0037] In step 45, it is checked if the time parameter T_a has reached a predetermined value T_{ac} determined therefor. When the answer is no, the control returns to step 41, and the steps 41-45 are repeated as long as the vehicle is running straight, until the time parameter T_a reaches the value T_{ac} . When the time parameter T_a reached the value T_{ac} , the control proceeds to step 46.

[0038] In step 46, the equivalent θ_o by steering angle of the neutral shift $\Delta\gamma$ is calculated as a mean value of each instant value θ during the time lapse corresponding to the time parameter value T_{ac} , as follows:

$$\theta_o = \sum \theta / N \quad (6)$$

[0039] In the above equation 6, N is a count number of the repetition of the process through steps 41-45 until T_a reaches T_{ac} by the repeated increment of ΔT .

[0040] In step 47, the newly obtained value of θ_o is stored or the already stored value of θ_o is renewed by the newly obtained θ_o , and thereafter the time parameter T_a and the sum of θ are reset to zero.

[0041] Thus, by the process of steps 41-47 being executed repetitively while the vehicle is running straight, after the warm-up of the yaw rate sensor 36, the neutral shift $\Delta\gamma$ of the yaw rate sensor 36 is always calibrated as a mean value thereof over a predetermined period during the straight running condition of the vehicle, and is compensated for as a modification of the value of the steering angle θ used for the estimation of the deviation $\Delta\gamma$ of the actual yaw rate γ detected by the yaw rate sensor relative to the theoretical standard yaw rate γ_t estimated from the vehicle speed and the steering angle, for the purpose of a behavior control of the vehicle.

[0042] The calculation of the neutral shift γ_d of the yaw rate sensor 36 in step 45 is executed according to the process shown in the flowchart of Fig. 4. According to this flowchart, in step 310, it is checked if the vehicle is stopped. When the answer is yes, the control proceeds to step 340, whereas when the answer is no, the control proceeds to step 320, and it is checked if the vehicle is running straight. When the answer is yes, the control proceeds to step 340, whereas when the answer is no, the control proceeds to step 330, wherein a time parameter T_b described hereinbelow is reset to zero, and the control of this sub-routine is ended.

[0043] In step 340, the time parameter T_b is incremented by a small amount ΔT .

[0044] In step 350, the output γ of the yaw rate sensor 36 is integrated such that the instant output value of γ is added up to the value of γ obtained up to the preceding

cycle.

[0045] In step 360, it is checked if the time parameter T_b has reached a predetermined value T_{bc} . When the answer is yes, the control proceeds to step 370, whereas if the answer is no, the control returns to step 310. Therefore, if the condition that the vehicle is at least stopped or running straight is lost after the control has started to circulate through steps 310-360 before the value T_{bc} is counted up, the process through this sub-routine is immediately ended.

[0046] In step 370, the value of the neutral shift γ_d is calculated as a mean value of each instant value of γ by the integrated value of γ being divided by a number N_b corresponding to the times of repetition of the process through steps 310-360.

[0047] In step 380, the newly obtained value of γ_d is stored or the value of γ_d obtained by the preceding process is replaced by the newly obtained value of γ_d , and thereafter the time parameter T_b and the integrated value of γ are both reset to zero.

[0048] In the driftout control in step 120 or step 150, as an embodiment, both of the rear left and rear right wheels 10RL and 10RR are braked to be applied with each controlled braking force such as F_{rl} and F_{rr} as shown in Fig. 6, so as to decelerate the vehicle, with a resultant effect that the driftout is suppressed. Further, in the embodiment shown in Fig. 6, the braking force F_{rl} applied to the rear left wheel 10RL is made larger than the braking force F_{rr} applied to the rear right wheel 10RR. Such an unbalance of the braking forces generates a yaw moment in the vehicle which is evaluated as M_{ad} around the center of gravity O_g of the vehicle. Therefore, the braking as a driftout control shown in Fig. 6 is more effective for the driftout control during a left turn of the vehicle. As is apparent, when the vehicle is turning to the right, a brake control with a larger braking force applied to the rear right wheel than to the rear left wheel is more effective as a driftout control.

[0049] Fig. 5 is a map showing an example of the relationship between the magnitude of the yaw rate deviation $|\Delta\gamma|$ and the magnitude of the braking force B_d generally applied to the rear wheels for suppressing a driftout.

[0050] In the left spin control of step 160, a braking is applied to the front right wheel 10FR as shown in Fig. 8. By a braking force being applied to the front right wheel 10FR, a clockwise turning moment is generated in the vehicle around the braked front right wheel 10FR by the inertia force of the vehicle concentrated at the center of gravity O_g of the vehicle, thereby generating an equivalent clockwise yaw moment M_{as} around the center of gravity O_g , acting against the spinning movement of the vehicle. As is also apparent, in the right spin control of step 130, a braking is applied to the front left wheel FL.

[0051] Fig. 7 is a map showing an example of the relationship between the magnitude of the yaw rate deviation $|\Delta\gamma|$ and the magnitude of the braking force B_s

applied to the front wheel at the outside of the turn in the left or right spin control.

[0052] Although the invention has been described in detail with respect to some preferred embodiments thereof, it will be apparent for those skilled in the art that various modifications are possible without departing from the scope of the present invention as defined by the appended claims.

Claims

1. A behavior control device of a vehicle having a vehicle body (12), a plurality of wheels suspended by the vehicle body, an engine, a steering system, and a brake system for selectively braking the wheels, the device comprising a means for detecting vehicle speed, a means for detecting steering angle, a means for detecting yaw rate of the vehicle, **characterised in that** it further comprises a means (30) for controlling the brake system according to a calculation based upon the vehicle speed detected by the vehicle speed sensor, the steering angle detected by the steering angle sensor (34), and the yaw rate detected by the yaw rate sensor (36) such that, when a deviation of the yaw rate detected by the yaw rate sensor relative to a standard yaw rate estimated from the vehicle speed and the steering angle increases beyond a threshold value, at least one of the wheels is braked by the brake system so as to generate a yaw moment in the vehicle body for decreasing the deviation of the yaw rate, wherein the control means temporarily increases the threshold value until the yaw rate sensor is warmed up
2. A behavior control device according to claim 1, wherein the warm-up of the yaw rate sensor is judged by a predetermined time having lapsed from the start of the engine.
3. A behavior control device according to claim 1, wherein the control means gradually decreases the magnitude of the increase of the threshold value according to the lapse of time from the increase thereof.
4. A behavior control device according to claim 1, wherein the control means calculates an equivalent of the steering angle by a neutral shift of the yaw rate sensor when the vehicle is running straight so as thereby to modify the steering angle detected by the steering angle sensor for a compensation of the neutral shift of the yaw rate sensor, and annuls the temporary increase of the threshold value at least for a predetermined period after an execution of the compensation even when the yaw rate sensor is not yet warmed up.

5. A behavior control device according to claim 4, wherein the control means calculates the equivalent of the steering angle by the neutral shift of the yaw rate sensor as a mean value of each instant value thereof during a predetermined unit period.
6. A behavior control device according to claim 4, wherein the control means modifies the value of the yaw rate detected by the yaw rate sensor so as to compensate for a neutral shift of the yaw rate sensor according to an output thereof while the vehicle is stopped or running straight.
7. A behavior control device according to claim 6, wherein the control means calculates the neutral shift of the yaw rate sensor as a mean value of an instant value thereof during a predetermined unit period.

Patentansprüche

1. Fahrverhaltenssteuervorrichtung eines Fahrzeugs mit einem Fahrzeugaufbau (12), einer Mehrzahl Rädern, die am Fahrzeugaufbau aufgehängt sind, einem Motor, einem Lenksystem und einem Bremssystem zum selektiven Bremsen der Räder, wobei die Vorrichtung eine Einrichtung zum Erfassen der Fahrzeuggeschwindigkeit aufweist, eine Einrichtung zum Erfassen des Lenkwinkels, eine Einrichtung zur Erfassung der Giergeschwindigkeit des Fahrzeugs, **dadurch gekennzeichnet, dass** die Vorrichtung ferner eine Einrichtung (30) zum Steuern des Bremssystems entsprechend einer Berechnung umfasst, welche auf der vom Fahrzeuggeschwindigkeitssensor erfassten Fahrzeuggeschwindigkeit, dem vom Lenkwinkelsensor (34) erfassten Lenkwinkel und der vom Giergeschwindigkeitssensor (36) erfassten Giergeschwindigkeit so basiert, dass dann, wenn eine Abweichung der vom Giergeschwindigkeitssensor erfassten Giergeschwindigkeit relativ zu einer aus der Fahrzeuggeschwindigkeit und dem Lenkwinkel geschätzten Standardgiergeschwindigkeit über einen Schwellenwert ansteigt, zumindest eines der Räder vom Bremssystem abgebremst wird, um im Fahrzeugaufbau ein Giermoment zum Senken der Abweichung der Giergeschwindigkeit zu erzeugen, wobei die Steuereinrichtung den Schwellenwert zeitweise anhebt, bis sich der Giergeschwindigkeitssensor aufgewärmt hat.
2. Fahrverhaltenssteuervorrichtung nach Anspruch 1, wobei das Aufwärmen des Giergeschwindigkeitssensors mittels einer ab dem Start des Motors abgelaufenen, festgelegten Zeit bewertet wird.
3. Fahrverhaltenssteuervorrichtung nach Anspruch 1

oder 2, wobei die Steuereinrichtung die Größe des Schwellenwert-Anhebens entsprechend der ab dem Anheben abgelaufenen Zeit schrittweise senkt.

4. Fahrverhaltenssteuervorrichtung nach Anspruch 1 oder 2, wobei die Steuereinrichtung ein Äquivalent des Lenkwinkels durch eine Nullpunktverschiebung des Giergeschwindigkeitssensors, wenn das Fahrzeug geradeaus fährt, berechnet, um dadurch den durch den Lenkwinkelsensor erfassten Lenkwinkel zwecks Kompensation der Nullpunktverschiebung des Giergeschwindigkeitssensors zu ändern, und das zeitweise Anheben des Schwellenwerts zumindest für eine festgelegte Dauer nach Ausführung der Kompensation aufhebt, wenn sich der Giergeschwindigkeitssensor noch nicht aufgewärmt hat.
5. Fahrverhaltenssteuervorrichtung nach Anspruch 4, wobei die Steuereinrichtung das Äquivalent des Lenkwinkels durch eine Nullpunktverschiebung des Giergeschwindigkeitssensors als Mittelwert aller seiner Momentanwerte während einer festgelegten Einheits-Dauer berechnet.
6. Fahrverhaltenssteuervorrichtung nach Anspruch 4, wobei die Steuereinrichtung den Wert der vom Giergeschwindigkeitssensor erfassten Giergeschwindigkeit ändert, um eine Nullpunktverschiebung des Giergeschwindigkeitssensors entsprechend seiner Ausgabe bei gestopptem oder geradeausfahrendem Fahrzeug zu kompensieren.
7. Fahrverhaltenssteuervorrichtung nach Anspruch 6, wobei die Steuereinrichtung die Nullpunktverschiebung des Giergeschwindigkeitssensors als Mittelwert aller seiner Momentanwerte während einer festgelegten Einheits-Dauer berechnet.

Revendications

1. Dispositif de commande du comportement d'un véhicule comportant une carrosserie de véhicule (18), une pluralité de roues suspendues par la carrosserie du véhicule, un moteur, un système de direction et un système de freinage destiné à freiner sélectivement les roues, le dispositif comprenant un moyen destiné à détecter la vitesse du véhicule, un moyen destiné à détecter l'angle de direction, un moyen destiné à détecter le mouvement de lacet du véhicule, **caractérisé en ce qu'il** comprend de plus un moyen (30) destiné à commander le système de freinage selon un calcul basé sur la vitesse du véhicule détectée par le capteur de vitesse du véhicule, l'angle de direction détecté par le capteur d'angle de direction (34), et le mouvement de lacet détecté par le capteur de mouvement de lacet (36) d'une

manière telle que, lorsqu'une déviation du mouvement de lacet détectée par le capteur de mouvement de lacet par rapport à un mouvement de lacet standard estimé à partir de la vitesse du véhicule et de l'angle de direction augmente au-delà d'une valeur de seuil, au moins une des roues est freinée par le système de freinage de façon à générer un moment de lacet dans la carrosserie du véhicule destiné à diminuer la déviation du mouvement de lacet, dans lequel le moyen de commande augmente temporairement la valeur de seuil jusqu'à ce que le capteur du mouvement de lacet soit réchauffé.

2. Dispositif de commande de comportement selon la revendication 1, dans lequel le réchauffement du capteur de mouvement de lacet est jugé par un temps prédéterminé s'étant écoulé depuis le démarrage du moteur.
3. Dispositif de commande de comportement selon la revendication 1 ou 2, dans lequel le moyen de commande diminue progressivement l'amplitude de l'augmentation de la valeur de seuil conformément à l'écoulement d'un temps depuis l'augmentation de celle-ci.
4. Dispositif de commande de comportement selon la revendication 1 ou 2, dans lequel le moyen de commande calcule un équivalent de l'angle de direction par un décalage du point mort du capteur de mouvement de lacet lorsque le véhicule roule en ligne droite de façon à de ce fait modifier l'angle de direction détecté par le capteur d'angle de direction pour une compensation du décalage du point mort du capteur de mouvement de lacet, et annule l'augmentation temporaire de la valeur de seuil pendant au moins une période prédéterminée après une exécution de la compensation même lorsque le capteur de mouvement de lacet n'est pas encore réchauffé.
5. Dispositif de commande de comportement selon la revendication 4, dans lequel le moyen de commande calcule l'équivalent de l'angle de direction par le décalage du point mort du capteur de mouvement de lacet comme valeur moyenne de chaque valeur instantanée de celui-ci pendant une période unitaire prédéterminée.
6. Dispositif de commande de comportement selon la revendication 4, dans lequel le moyen de commande modifie la valeur du mouvement de lacet détectée par le capteur du mouvement de lacet de façon à compenser un décalage du point mort du capteur de mouvement de lacet conformément à une sortie de celui-ci alors que le véhicule est arrêté ou roule en ligne droite.

7. Dispositif de commande de comportement selon la revendication 6, dans lequel le moyen de commande calcule le décalage du point mort du capteur de mouvement de lacet comme valeur moyenne d'une valeur instantanée de celui-ci pendant une période unitaire prédéterminée. 5
